is a prospective technology for soft tissue modification. The prototype of the first generation e-KTP system (e-KTP 1.0) was shown to be effective for subepithelial connective tissue reinforcement in a porcine model of periodontal ligament (PDL) recession \[[@CR1]\]. In the e-KTP 1.0 system, a high-frequency piezoelectric device with an output of 400 V was used to deliver acoustic energy to the root surface. The piezoelectric device was introduced to the root surface through a microgrooved titanium fiber post that was used as an anchor to the root surface. The microgrooves were created by a diamond-impregnated cutting tip attached to a pilot drill. During the treatment, the e-KTP device was positioned at the apical root surface and acoustic energy was delivered for 30 s to the root surface. This was followed by the delivery of a laser pulse for 60 s. The laser pulse duration was set to be 10 times longer than the duration of the acoustic energy and the energy delivered in each pulse was 5 J.

The beam diameter was set to be 15 mm and the tip of the laser beam was aligned to the axis of the fiber post. This study evaluated the efficacy of the e-KTP 1.0 system for subepithelial connective tissue reinforcement in a human clinical study. The study was designed as a split-mouth study. The left and right sides of each subject were randomly assigned to the test and control sides. For each subject, the test side was treated with e-KTP and the control side was treated with mechanical debridement (MD) only. Clinical and radiographic examinations were performed at baseline, 3 months after the treatment, and 6 months after the treatment. Twelve patients were enrolled in the study. All patients were informed of the risks and benefits of the treatment and signed the informed consent form. The study protocol was approved by the Ethics Committee of the University of Miyazaki. The study was conducted in accordance with the Helsinki Declaration. The inclusion criteria were as follows: (1) PDL recession of at least 2 mm; (2) the presence of furcation involvement; (3) at least 5 mm of root surface exposed; (4) at least 20 teeth; (5) the presence of at least 2 teeth in the mandibular arch and at least 3 teeth in 82157476af
